*Some rigourous results in a Modified Bak-Sneppen Model*

**Abstract**

Bak-Sneppen model has been proposed in the Statistical Physics literature as a model of self-organised criticality. However, rigourous mathematical derivation of the self-organised criticality has not yet been achieved. In this talk, I will discuss the results which have been proved rigourously and state other conjectures. Finally, I will show that in a modified model, similar results can be proved using very simple arguments.

10:40  Rongfeng Sun  

*Continuum Limits of the Random Pinning Model Under Weak Coupling*

**Abstract**

We study random pinning models, where the return time distribution of the underlying renewal process is regularly varying with exponent \(-(1 + \alpha)\) for some \(\alpha > 1/2\). We show that, if we let the system size tend to infinity, while rescaling the disorder strength and bias accordingly, then the partition functions of the random pinning models have non-degenerate limits that can be expressed in terms of Wiener chaos expansions. For \(\alpha > 1\), these limits are exponentials of Brownian motions with drift. For \(\alpha \in (1/2, 1)\), these limits can still be interpreted as partition functions, which we use to construct a family of continuum random pinning models. (Joint work with Francesco Caravenna and Nikos Zygouras)

11:45  Rohini Kumar  

*Large deviations in multi-time scale stochastic systems*

**Abstract**

Using the theory of viscosity solutions of partial differential equations, we prove large deviation results for multi-time scale stochastic systems. We initially look at two time scale stochastic systems where the fast and slow processes are diffusions given by coupled SDEs. This problem was motivated from finance when pricing options close to maturity under the assumption of fast mean-reverting stochastic volatility. This was joint work with Jean-Pierre Fouque and Jin Feng. We will also look at possible extensions of these results to a two time scale system where the fast process is a jump-diffusion process.
12:25  Hubert Lacoin  

Non-monotonicity for biased random walk on trees without leaves

Abstract
We consider a random walk on an infinite rooted tree biased away from the root. We exhibit a family of trees for which the asymptotic speed of the walk is not an increasing function of the bias.

14:30  Anita Winter  

Convergence of bi-measure R-trees and the subtree prune process

Abstract
In 1998 Aldous and Pitman constructed a tree-valued Markov chain by pruning off more and more subtrees above randomly chosen edges of a Galton-Watson tree. More recently Abraham, Delmas and He considered a similar process, where the cut-points are chosen in a degree-dependent way. In the same spirit prunings of continuum trees were studied by various authors. However, so far no precise link between the prunings of discrete and continuum trees has been given.

In this talk we encode trees as metric measure spaces and equip them additionally with a pruning measure, and provide a topology on the space of bi-measure R-trees. We then construct THE subtree prune process and show that convergence of initial states implies convergence of the whole bi-measure valued paths.
(joint work with Wolfgang Lhr and Guillaume Voisin)

15:10  Akira Sakai  

Recent progress in the lace expansion

Abstract
The lace expansion has been a powerful tool to rigorously investigate critical behavior in high dimensions. For example, self-avoiding walk is a statistical-mechanical model for linear polymers and exhibits critical behavior when the fugacity $\mu$ approaches its critical value $\mu_c$: $\chi_\mu \equiv \sum_{\omega: o \rightarrow} \mu^{\abs{\omega}}1_{\{\omega \text{ is SAW}\}} \approx (\mu_c - \mu)^{-\gamma}$. By the lace expansion initiated by Brydges and Spencer in 1980s and then developed by Hara and Slade in 1990s, it is now known that the susceptibility $\chi_\mu$ for nearest-neighbor SAW above 4 dimensions diverges as a multiple of $(\mu_c - \mu)^{-1}$. The key idea is to rewrite $1_{\{\omega \text{ is SAW}\}}$ by $\prod_{0 \leq s < t \leq \abs{\omega}} (1 - \delta_{\omega_s, \omega_t})$ and expand the product in a nicely way so that the self-avoiding constraint is partially restored.
The number of models/problems to which the lace expansion can be applied is getting larger, but it is still limited. The goal of my talk is to extend the range of applicability by considering the following two problems above 4 dimensions.

- Non-intersection probability of two random walks starting from $o \in \mathbb{Z}^d$.
- Asymptotic behavior of the critical two-point function for the $\varphi^4$ model in $\mathbb{Z}^d$.

The former is solved by a simple extension of the aforementioned idea for SAW. The latter is solved by approximating the $\varphi^4$ model by a certain Ising model on $\mathbb{Z}^d \times \{1, \ldots, N\}$ and then using the lace expansion for the Ising model. I will explain the analysis as long as time permits.

10:00 Alexander Drewitz
Asymptotic behavior of the critical parameter for level-set percolation of the Gaussian free field

Abstract
We consider the Gaussian free field in $\mathbb{Z}^d$, $d \geq 3$. It is known that there exists a non-trivial phase transition for its level set percolation; i.e., there exists a critical parameter $h_*(d) \in [0, \infty)$ such that for $h < h_*(d)$ the excursion set above level $h$ does have a unique infinite connected component, whereas for $h > h_*(d)$ it consists of finite connected components only.

We investigate the asymptotic behavior of $h_*(d)$ as $d \to \infty$ and give some ideas on the proof of this asymptotics.
(Joint work with P.-F. Rodriguez)

10:40 Anup Biswas
Law of Large Numbers for Queues under Earliest Deadline First Scheduling

Abstract
In recent days, queuing systems with impatient customers have gain considerable interest. In this talk we consider queuing systems in which each arriving customer has a deadline and the customer leaves the system if he/she does not reach the server before his/her deadline elapses. Earliest-Deadline-First (EDF) policy has proven optimal in certain sense for these systems. We start with a single server queuing system working under EDF scheduling policy and establish the LLN limits for the queue measures and reneged customers. We show that the LLN limits of queue lengths are related to a Skorohod reflection problem in a time-varying domain. Extension of these results to other queuing systems will also be discussed.

11:45 Daisuke Shiraishi
Non-intersecting random walks in low dimensions

Abstract
We consider two random walks conditioned never to intersect in $\mathbb{Z}^2$. We show that each of them has infinitely many global cut times with probability one. In fact, we prove that the number of global cut times up to $n$ grows like $n^{3/8}$. Next we consider the union of their trajectories to be a random subgraph of $\mathbb{Z}^2$ and show the subdiffusivity of the simple random walk on this graph.
Infinite Color Urn Models

Abstract
In this presentation we introduce a new type of urn model with infinitely but countably many colors of balls. We focus mainly on colors indexed by the $d$-dimensional integer lattice and replacement matrices associated with bounded increment random walks on it. We prove the central and local limit theorems for the expected configuration of the urn and show that irrespective of the transience or recurrence of the underlying random walks, there exists universal centering and scaling of the configuration giving appropriate Gaussian limits.

Convergence of path measures with mean-field type interactions

Abstract
We consider long time behavior of Gibbs measure on three dimensional Brownian paths with mean-field type Hamiltonian with Coulomb interaction. The free energy admits a well-studied variational formula (Donsker-Varadhan [1983], Lieb [1976]). It turns out that the long time asymptotics of the path measure converges to a mixture of the minimizers of the free energy variational formula. This model is related to the Polaron problem, where the behavior of the path measures (in a certain regime known as ‘strong coupling’) is of interest and possesses a number of open problems. This is joint work (in progress) with Erwin Bolthausen (Zrich)

Energy Landscape for large average submatrices in Gaussian random matrices

Abstract
The problem of finding large average submatrices of a real-valued matrix arises in the exploratory analysis of data from a variety of disciplines, ranging from genomics to social sciences. We provide a detailed asymptotic analysis of large average submatrices of an $n \times n$ Gaussian random matrix. For fixed $k$ we identify the average and the joint distribution of the $k \times k$ submatrix with largest average value. As a dual result, we establish that, for any given $\gamma_1 > 0$, the size of the largest square sub-matrix with average bigger than $\gamma_1$ is, for large $n$, equal to one of two consecutive integers near $4\gamma_1^{-2}(\log n - \log \log n)$.

We then turn our attention to submatrices with dominant row and column sums, which arise as the local optima of iterative search procedures for large average submatrices. For fixed $k$, we identify the average and joint distribution of a typical $k \times k$ submatrices with dominant row and column sums, and we carry out a detailed analysis of the number $L_n(k)$ of such submatrices, beginning with the mean and variance of $L_n(k)$ which has a very atypical behavior. In particular, for $k = 2$ and $k = 3$, the order of the means are $o(n^2)$ and $o(n^3)$, while the variances are $n^{8/3}$ and $n^{9/2}$, respectively, with logarithmic corrections. Our principal result is a Gaussian central limit theorem for $L_n(k)$ that is based on a new variant of Stein’s method.
10:00  Codina Cotar  

*On finite and infinite-bodied optimal transportation with Coulomb cost*

**Abstract**

In recent joint work with Gero Friesecke and Claudia Klueppelberg (2011, 2013), we discovered that in a natural scaling limit, the celebrated Hohenberg-Kohn density functional from electronic structure theory reduces to an optimal transport problem. We also proved a transferable main theorem independently of Coulomb/electrons of general interest in optimal transport, namely weak* density of smooth plans with given marginal in the set of all such plans.

In new joint work with Gero Friesecke and Brendan Pass (2013), we find by means of techniques from exchangeable processes in probability theory an explicit solution to the infinite marginals OT problem with Coulomb cost. Moreover, we discuss by a combination of probabilistic and optimal transport methods the answer to the question of uniqueness for the many-bodied optimal transport problem with Coulomb cost.

10:40  Ryoki Fukushima  

*Localization of Brownian motion in random potentials*

**Abstract**

We consider the Brownian motion interacting with a random potential. More precisely, we define a probability on the path space by weighting the Wiener measure by the Feynman-Kac functional. Under this measure, the process tends to go to a place where the random potential attains atypically small value. I will present several formulations and results on the path localization.

11:45  Ghurumuruhan Ganesan  

*Convergence rate of locally determinable Poisson functionals*

**Abstract**

In this talk, we study convergence rate of locally determinable functionals of Poisson processes. Let \( \mathcal{N} \) denote a realization of a homogenous Poisson point process in \( \mathbb{R}^d \) with intensity \( \lambda \) and place an independent mark \( t_x \) on each point \( x \) of \( \mathcal{N} \). Let \( \mathcal{N}_M \) be the resulting marked process and let \( f(x) = f(x, \mathcal{N}_M), x \in \mathcal{N} \) be a locally determinable function. Letting \( W = [-1/2, 1/2]^d \), we evaluate the rate of convergence of

\[
\frac{1}{n^d} \sum_{x \in nW \cap \mathcal{N}} f(x)
\]

to its mean as \( n \to \infty \), in terms of the decay rate of radius of determinability. We apply our results to determine the rate of convergence of functionals of Poisson Voronoi tessellation and the Poisson Boolean model.
Neeraja Sahasrabudhe  
*Covariance Realization Problem for Spin Systems*

**Abstract**

Deriving the form of the optimal solution of a *maximum entropy problem*, we obtain an infinite family of linear inequalities characterizing the polytope of spin correlation matrices. For $n \leq 6$ the facet description of such polytope is provided through a minimal system of Bell-type inequalities.

An explicit method to determine the matrix that parametrizes the maximum entropy measure is described and algorithms to obtain this matrix (consequently the maximum entropy measure) are discussed.

Omer Angel  
*Half planar random maps and percolation exponents*

**Abstract**

Certain half planar random maps are known to have a certain "domain Markov" property. I will describe work with Nicolas Curien where we exploit this property to derive various exponents associated with critical percolation on the random maps.

Antar Bandyopadhyay  
*Nearest Neighbor Algorithm for Mean Field Traveling Salesman Problem*

**Abstract**

In this talk we will consider the mean field traveling salesman problem, where the intercity distances are taken to be i.i.d. with some distribution $F$. This paper focuses on the *nearest neighbor tour* which is to move to the nearest non-visited city and we show that if $F$ admits a continuous density at 0 which takes a strictly positive value at 0 then the total length of the nearest neighbor tour, asymptotically almost surely scales as $\log n$. Similar result is known for Euclidean TSP and nearest neighbor tour. We further derive the limiting behavior of the total length of the nearest neighbor tour for a general distribution function $F$ with certain assumptions and show that its asymptotic properties are determined by the scaling properties of the density of $F$ at 0.
10:00 Manjunath Krishnapur  
On zeros of random functions

Abstract
We will present some recent results in the study of zeros of random polynomials and related random functions.

10:40 Kumarjit Saha  
Random directed forest and the Brownian web

Abstract
Consider the $d$ dimensional lattice $\mathbb{Z}^d$ where each vertex is open or closed with probability $p$ or $1 - p$ respectively. An open vertex $\mathbf{u} := (u(1), u(2), \ldots, u(d))$ is connected by an edge to another open vertex which has the minimum $L_1$ distance among all the open vertices with $x(d) > u(d)$. It is shown that this random graph is a tree almost surely for $d = 2$ and $3$ and it is an infinite collection of disjoint trees for $d \geq 4$. In addition for $d = 2$, we show that when properly scaled, family of its paths converges in distribution to the Brownian web.

11:45 Adrian Roellin  
Testing dense graphs for homogeneity

Abstract
A very basic problem and starting point in network analysis is to test whether a given network is compatible with a homogeneous Erdős-Rényi random graph model, where two nodes are connected with a fixed probability $p$, independent of all other connections. Several test statistics have been proposed to tackle this problem: diameter of the biggest component, maximum degree, number of triangles, average path length, clustering coefficient, etc. Whereas (asymptotic) distributions of these statistics under the null hypothesis can and have been calculated, it remains mostly unclear how they perform under alternative models. We propose a new test statistic that is based on the number of edges and number of 4-cycles, which asymptotically can detect any heterogeneity in the edge probabilities in the case of dense graphs, that is, the case when the average degree grows linearly with the number of nodes. The proofs are based on bivariate normal approximation via Stein’s method (which will not be discussed in this talk) and dense graph limit theory (which will be briefly introduced).
12:25 Makiko Sasada  

*Mixing rates and hydrodynamics for stochastic energy exchange models with degenerate rate functions*

**Abstract**

In recent years, stochastic energy exchange systems of locally confined particles in interaction have been studied intensively, as accessible models for the rigorous study of the derivation of Fourier’s law from microscopic dynamics of mechanical origin. As a generalization of them, Alexander Grigo, Konstantin Khanin and Domokos Szsz introduced a class of Markov jump processes of energies. In this talk, I will consider a special class of these processes where the rate function of the energy exchange does not have a uniform lower bound. As pointed out by Grigo and his co-authors, such a rate function naturally appears in the models that originate from mechanical models, but it leads to serious technical complications in the analysis of the spectral gap. I will give a lower bound estimate of the spectral gap and examples belonging to the class. Their macroscopic properties and scaling limits will be also discussed.

14:30 Arnab Ganguly  

*A few approaches to large deviations for stochastic differential equations*

**Abstract**

In this talk I will give an overview of some general approaches to study large deviations of stochastic differential equations (SDEs). These methods also extend to the case of infinite-dimensional SDEs. Since many Markov processes can be represented as solutions of appropriate SDEs, these methods provide a systematic way to investigate large deviation principle of a large class of Markov processes.

15:10 Sreekar Vadlamani  

*Scaling limits for critical quantum random graphs*

**Abstract**

Quantum random graphs, which are a generalization of Erds-Renyi random graphs, were first introduced by Ioffe and Levit in 2007. We study the behavior of appropriately scaled quantum random graphs inside the "critical window". In particular, we prove that the rescaled sizes of components of quantum random graphs converge in distribution to excursion-lengths of a certain process related to Brownian motion. These results are generalization of Aldous’ results on scaling limits of component sizes of Erds-Renyi random graphs, to the case of quantum random graphs.
Obliquely reflecting Brownian motion in fractal domains

Abstract
The definition of obliquely reflecting Brownian motion (ORBM) in terms of the reflection vector field on the boundary is not meaningful for domains with rough (fractal) boundaries. We introduce an alternative way to define ORBM in non-smooth (possibly fractal) bounded simply connected planar domains, and show that this definition is in a suitable sense robust. Key tools are a parametrization of ORBMs in the unit disc, which may be of independent interest, and conformal mappings. This is joint work with K. Burdzy, Z.Q. Chen and D. Marshall.

Thick points for the Gaussian Free Field in 4 dimensions

Abstract
We study the fractal properties of the thick points of the 4-dimensional massive Gaussian Free Field. We adopt the definition of Gaussian Free Field (GFF) on \( \mathbb{R}^4 \) introduced by Chen and Jakobson (2012) viewed as an abstract Wiener space with underlying Hilbert space given by the Sobolev space \( H^2(\mathbb{R}^4) \). In this talk we show that for \( 0 \leq a \leq 4 \) the Hausdorff dimension of the set of \( a \)-high points is \( 4 - a \). The set of thick points can be related to the support of the Liouville quantum gravity measure in 4 dimensions introduced by Chen and Jakobson (2012). These results can be seen as an extension of the results obtained in 2 dimensions by Hu, Miller and Peres (2010) for thick points of the GFF on a domain. We also review some results on 2-dimensional Liouville quantum gravity measure introduced by Duplantier and Sheffield (2011).

This is a joint work with Alessandra Cipriani.

Dual processes and exact correlation functions.

Abstract
Duality is a powerful tool to analyse stochastic dynamics, by which the original process is studied via a simpler one, called a “dual process”. In this talk I will review a new method to construct a dual process which I recently introduced in collaboration with J. Kurchan and F. Redig. The method combines insights of probability theory, mathematical physics and the theory of Lie algebra. Applications will be shown in the context of heat conduction models and for multi-type population models. In both case duality yields an exact solution, and explicit expressions for the process correlation functions can be found.
12:25  Tom Alberts  

*Dimension Spectrum of SLE Boundary Collisions*

**Abstract**

In the range $4 < \kappa < 8$, the intersection of the Schramm-Loewner Curve (one of the central objects in the theory of 2-D Conformally Invariant Systems) with the boundary of its domain is a random fractal set. After reviewing some previous results on the dimension and measure of this set, I will describe recent joint work with Ilia Binder and Fredrik Viklund that partitions this set of points according to the generalized “angle” at which the curve hits the boundary, and computes the Hausdorff dimension of each partition set. The Hausdorff dimension as a function of the angle is what we call the dimension spectrum.

14:30  Kshitij Khare  

*Convergence for some multivariate Markov chains with polynomial eigenfunctions.*

**Abstract**

In this talk, we will present examples of multivariate Markov chains for which the eigenfunctions turn out to be well-known orthogonal polynomials. This knowledge can be used to come up with exact rates of convergence for these Markov chains. The examples include the multivariate normal autoregressive process and simple models in population genetics. Then we will consider some generalizations of the above Markov chains for which the stationary distribution is completely unknown. We derive upper bounds for the total variation distance to stationarity by developing coupling techniques for multivariate state spaces. The talk is based on joint works with Hua Zhou and Nabanita Mukherjee.

15:10  Arijit Chakrabarty  

*Limiting spectral distribution for Wigner matrices with dependent Entries*

**Abstract**

In this work we show the existence of limiting spectral distribution of a symmetric random matrix whose entries come from a stationary Gaussian process with covariances satisfying a summability condition. We provide an explicit description of the moments of the limiting measure. We also show that in some special cases the Gaussian assumption can be relaxed. The description of the limiting measure can also be made via its Stieltjes transform which is characterized as the solution of a functional equation. In two special cases, we get a description of the limiting measure - one as a free product convolution of two distributions, and the other one as a dilation of the Wigner semicircular law. This is a joint work with Rajat S. Hazra and Deepayan Sarkar.
